

# DelSig\_16Channel Example Project

## 1.10

## Features

- 12-bit Delta-Sigma ADC with 16 multiplexed single-ended inputs.
- The Analog Mux and ADC are controlled in hardware and ADC results stored in memory using DMA – No firmware intervention.
- Switch can be used to cycle through readings displayed on LCD.

## General Description

This example project is also a PSoC Creator starter design for PSoC 3/5LP devices. It uses the Delta Sigma ADC, DMA, and other hardware to sequence, sample, and store 16-channels of input data in memory without CPU intervention.

## Development Kit Configuration

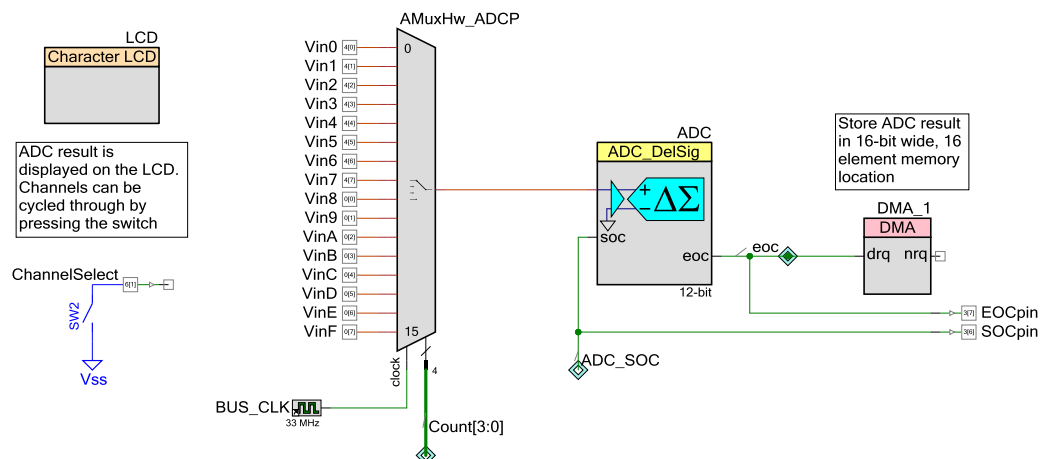

The following configuration instructions provide a guideline to test this design. For simplicity, the instructions describe the stepwise process to follow when testing this design with the PSoC Development Kit (CY8CKIT-001) board, but can be generalized for the PSoC 3 Development Kit (CY8CKIT-030) as well.

1. Set LCD power jumper J12 to ON position, assign SW3 to the 5V position, and leave the rest of the board at default configuration.
2. Observe the mux channel select signals P3[3:0], the ADC SOC P3[6] and the ADC EOC P3[7] on an oscilloscope.
3. Connect P6[1] to SW2 on the board, and ensure that a character LCD is connected to P2[6:0].
4. If testing the project with Analog inputs, connect the first 8 to P4[7:0] and the other 8 to P0[7:0]. Ensure that these voltages are between 0 and 2.048V – the input range set for the ADC.
5. Build the DelSig\_16Channel project and then program the hex file to the PSoC device using the MiniProg3. After programming is complete, disconnect the MiniProg3.
6. Reset the PSoC device.

## Project Configuration

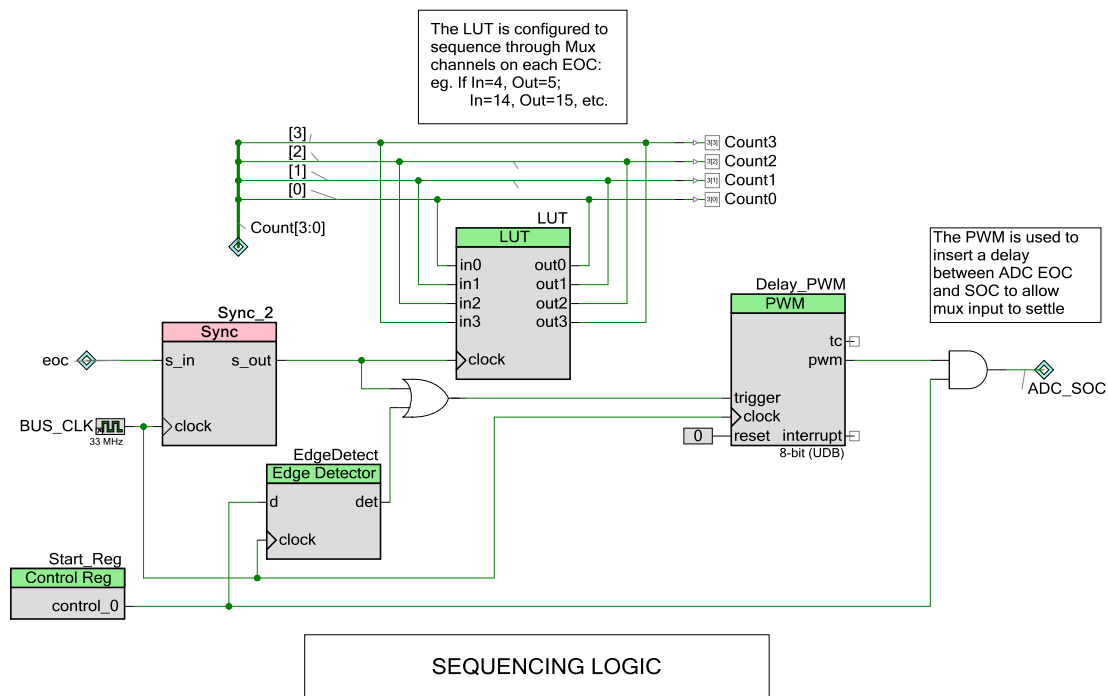

The top design schematic is shown in Figure 1. The 16 analog inputs are fed into the Analog hardware mux whose output is connected to the single-ended 12-bit ADC. The ADC is configured (Figure 2) in Single Sample mode – the Start-of-Conversion (SOC) input to the ADC needs to be triggered for each sample. This SOC signal is generated by delaying the ADC End-of-Conversion (EOC) output by 1.5  $\mu$ s using the PWM. This delay allows the mux inputs to settle when switching between inputs. The EOC is thus used as a trigger for the PWM in One-shot-multi-trigger mode (Figure 4). It also serves as the DRQ signal for the DMA and clock for the LUT. So after each ADC conversion, the DMA transfers the ADC output to memory, and the LUT updates its output. The Start\_Reg control register gates the ADC SOC, and is set to 1 at the start to allow for ADC conversion.

## SEQUENCING LOGIC

Figure 1. Top Design Schematic

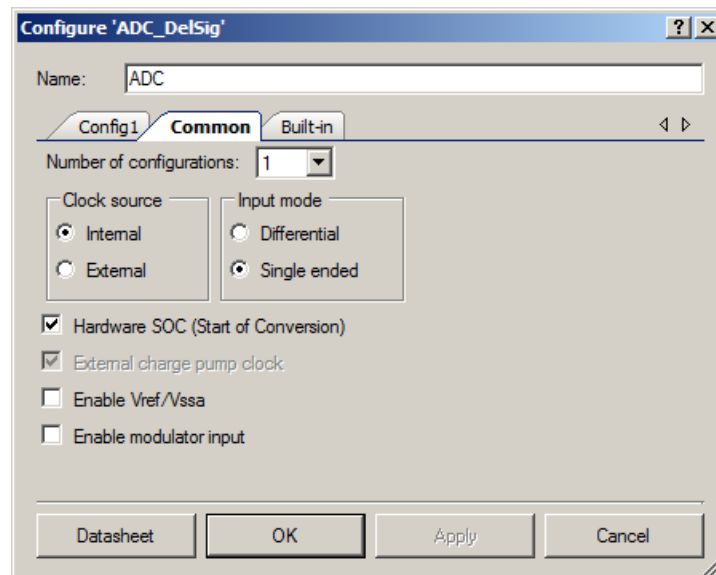

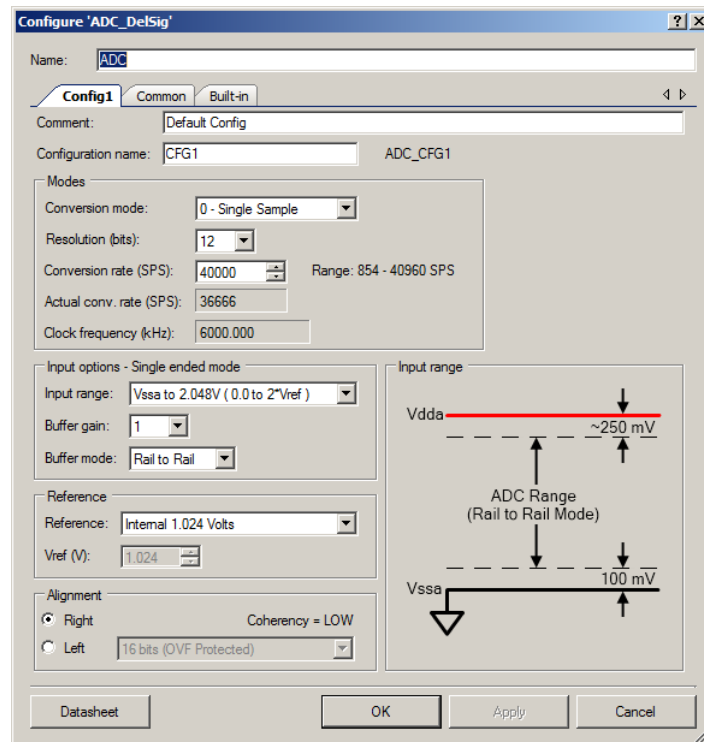

Figure 2. ADC\_DeISig Component Configuration

As shown in Figure 2, the input range of the ADC is 0-2.048V, and the input rail-to-rail buffer is enabled. The conversion rate is set to 41 ksp/s. This is for all 16 channels, so factoring in the delay between EOC and SOC, the expected per-channel conversion rate is roughly 2.4 ksp/s. However, the actual sampling rate is marginally lower, due to the overhead when starting the ADC and the finite clock divider used to get the conversion rate desired.

Datasheet OK Apply Cancel

Figure 3. Look-Up Table configuration

The LUT is set up to cycle sequentially through the mux channels 0-15 on each ADC EOC pulse (Figure 3).

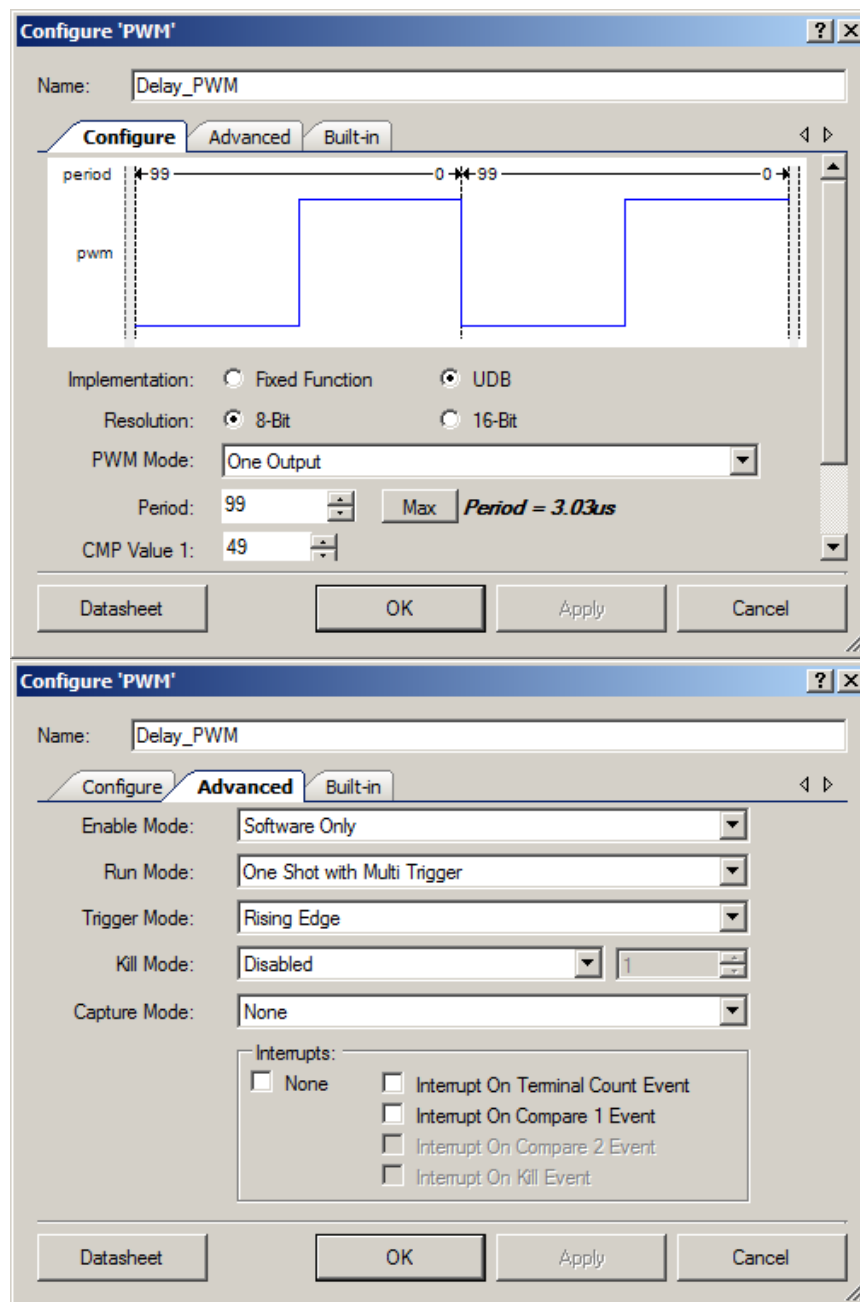

Figure 4. PWM component configuration

As seen in Figure 4, the PWM is set up to have a one-shot multi-trigger run mode. The duty cycle is kept as 50%, but its value actually does not matter. What matters is the compare type which is set to 'greater than'. Since the PWM counts down from the 'Period' value, this ensures that the PWM output generates a rising edge each time the period is reloaded – that is, for every terminal count event. Since the Start\_Reg is initially set to 1, this rising edge causes the ADC to start conversion.

## Project Description

In the main function all components are started. Also, the DMA is configured to transfer the ADC output to memory.

As explained in the previous section, the ADC conversion is controlled in hardware. In the 'forever' loop in main, the ADC output for a single channel is displayed and continually updated on the Character LCD. The various channels of the mux can be cycled through by pressing the SW2.

## Expected Results

- The ADC output results as displayed on the LCD should match the analog inputs given (if any).
- The count value P3[3:0] should continuously cycle between 0-15 at a frequency of approximately 17.1 kHz.
- The ADC SOC and EOC signals should generate logic high pulses at 34.4 kHz frequency.
